

AI Interaction Log

Author: Bryce **Date:** 2026-09-25 **AI Tool:** Claude (Cowork)

Task / Prompt

Explain what the “migration scripts” mentioned in the database issue are and what the term means.

Context / Findings

- General, well-established software-engineering concept; no external sources required.
- Tied directly to the DB issue’s task list and to the assignment’s “runs from a clean checkout” requirement.
- The specific tool depends on the DBMS/framework the team eventually chooses.

AI Output / Actions

- A migration script is a version-controlled file that defines how the database structure changes, one step at a time, committed alongside the code.
- Schema changes are written as code (raw SQL or a framework’s migration format) instead of being applied manually in a GUI, so every teammate gets an identical database.
- Each migration is one incremental change (e.g. “create users/profiles/resumes tables”, later “add a column”); the DB tracks which migrations have been applied so none run twice; many support an “undo”/down step for rollback.
- Example given: a raw SQL `001_create_users.sql` creating the `users` table (id PK, unique email, password_hash, role default, timestamps).
- Common framework tools noted: Django makemigrations/migrate, Rails Active Record migrations, Node Knex/Prisma, Spring Flyway/Liquibase.
- Tied back to the assignment’s “runs from a clean checkout” requirement: a teammate or the TA can clone the repo, run the migrations, and get a working DB in one step — no manual schema drift.
- Conclusion: “write migration scripts for the Sprint 1 tables” = create the files/commands that build `users`, `profiles`, `resumes`, commit them, and document the run command.

Decision

N/A

Reflection

Bryce: This helped me understand what migration scripts are, why it needed to be an item on the DB issue todo list, and why we need it in the first place.
